## **CSE 102**

## **Final Review Problems**

Be sure to review all prior homework assignments, midterm exams, and their solutions. Review all examples covered in class.

- 1. Suppose T(n) satisfies the recurrence T(n) = 3T(n/4) + F(n), where F(n) itself satisfies the recurrence  $F(n) = 5F(n/9) + n^{3/4}$ . Find a tight asymptotic bound for T(n). Be sure to fully justify each use of the Master Theorem. (Hint:  $\log_9(5) < 3/4 < \log_4(3)$ .)
- 2. Suppose we are given 4 gold bars (labeled 1, 2, 3, 4), one of which *may* be counterfeit: gold-plated tin (lighter than gold) or gold-plated lead (heavier than gold). Again the problem is to determine which bar, if any, is counterfeit and what it is made of. The only tool at your disposal is a balance scale, each use of which produces one of three outcomes: tilt left, balance, or tilt right.
  - a. Use a decision tree argument to prove that at least 2 weighings must be performed (in worst case) by any algorithm that solves this problem. Carefully enumerate the set of possible verdicts.
  - b. Determine an algorithm that solves this problem using 3 weighings (in worst case). Express your algorithm as a decision tree.
  - c. Find an adversary argument that proves 3 weighings are necessary (in worst case), and therefore the algorithm you found in (b) is best possible. (Hint: study the adversary argument for the min-max problem discussed in class to gain some insight into this problem. Further hint: put some marks on the 4 bars and design an adversary strategy that, on each weighing, removes the fewest possible marks, then show that if the balance scale is only used 2 times, not enough marks will be removed.)
- 3. Recall the coin changing problem again. Given denominations  $d = (d_1, d_2, ..., d_n)$  and an amount N, determine the number of coins in each denomination necessary to disburse N units using the fewest possible coins. Assume that there is an unlimited supply of coins in each denomination. Prove that the greedy strategy works for any amount N with the coin system d = (1, 5, 10, 25).
- 4. Scheduling to Minimize Average Completion Time: (This is problem 16-2a on page 402 of CLRS.) Suppose you are given a set  $S = \{a_1, a_2, ..., a_n\}$  of tasks, where task  $a_i$  requires  $p_i$  units of processing time to complete, once it has started. You have one computer on which to run these tasks, and the computer can run only one task at a time. Let  $c_i$  be the *completion time* of task  $a_i$ , that is, the time at which task  $a_i$  completes processing. Your goal is to minimize the average completion time, that is to minimize the quantity  $(1/n) \sum_{i=1}^n c_i$ . For example, suppose there are two tasks,  $a_1$  and  $a_2$ , with  $a_2$  and  $a_3$  and  $a_4$  and the average completion time is  $a_4$  and the average completion time is  $a_4$  and the average completion time is  $a_4$  and  $a_4$  and the average completion time is  $a_4$  and  $a_4$  and the average completion time is  $a_4$  and  $a_4$  and  $a_4$  and the average completion time is  $a_4$  and  $a_4$  and  $a_4$  and the average completion time is  $a_4$  and  $a_4$  and  $a_4$  and  $a_4$  and the average completion time is  $a_4$  and  $a_4$  and  $a_4$  and  $a_4$  and  $a_4$  and  $a_4$  and  $a_4$  and the average completion time is  $a_4$  and  $a_4$  and  $a_4$  and  $a_4$  and  $a_4$  are average completion time is  $a_4$  and  $a_4$  and  $a_4$  and  $a_4$  are average completion time is  $a_4$  and  $a_4$  and  $a_4$  are average completion time is  $a_4$  and  $a_4$  are average completion time is  $a_4$  and  $a_4$  are average completion time is  $a_4$  and  $a_4$  are average completion time.

Give an algorithm that schedules the tasks so as to minimize the average completion time. Each task must run non-preemptively, that is, once task  $a_i$  is started, it must run continuously for  $p_i$  units of time. Prove that your algorithm minimizes the average completion time, and state the running time of your algorithm.

- 5. Let  $B = b_1 b_2 \dots b_n$  be a bit string of length n. Consider the following problem: determine whether or not B contains 3 consecutive 1's, i.e. whether B contains the substring "111". Consider algorithms that solve this problem whose only allowable operation is to peek at a bit.
  - a. Suppose n = 4. Obviously 4 peeks are sufficient. Give an adversary argument showing that in general, 4 peeks are also necessary.
  - b. Suppose  $n \ge 5$ . Give an adversary argument showing that  $4 \cdot \lfloor n/5 \rfloor$  peeks are necessary. (Hint: divide B into  $\lfloor n/5 \rfloor$  4-bit blocks separated by 1-bit gaps between them. Thus bits 1-4 form the first block, and bit 5 is the first gap. Bits 6-9 form the next block and bit 10 is the next gap, etc.. Any leftover bits form a separate block. Now run the adversary from part (a) on each of the 4-bit blocks.)
